Cal III: Functions & Gradient

Functions of Several Variables:

- Just as a typical one-dimensional function maps an input (x, horizontal axis) to an output (y, vertical axis), so a two-dimensional function maps inputs (x *and* y) to an output (z, height). All rules still apply to higher-order functions and many properties scale.

Directional Derivatives and Gradient:

- Directional derivatives describe how rapidly a function is changing in a certain direction as defined by the unit vector of v. A typical partial derivative is a specific directional derivative, with the unit vector in the i or j direction. If you are given a vector **u** that is not a unit vector, then the unit vector **v** would be **u/**[**u**].
- Gradients define the rate of change in the direction that water would flow along the surface; that is, the direction of greatest increase/decrease at a specific point. A vector orthogonal to the gradient experiences no change. This is analogous to a contour map.

The gradient of f is noted by the Greek letter "del":

$$\nabla f = \frac{\partial f}{\partial x} i + \frac{\partial f}{\partial y} j$$

The directional derivative at point P_0 in the direction of $u = \frac{v}{|v|}$:

$$\left(\frac{\partial f}{\partial s}\right)\Big|_{u, P_0} = (\nabla f)|_{P_0} \cdot u$$

Extreme Values:

- First, determine the location (a, b) such that $f_x = f_y = 0$. *Note: this often requires factoring.*
- Next, apply the second derivative test to determine which feature is located at (a, b).
- If the discriminant of f is < 0 (negative), f has a saddle point at (a, b).
- If the discriminant of f is $= 0$, the test is inconclusive.
- If the discriminant of f is > 0 (positive), evaluate the following rules:
  - If $f_{xx} < 0$ (negative) then there is a local maximum at (a, b).
  - If $f_{xx} > 0$ (positive) then there is a local minimum at (a, b).
- The discriminant is defined as $f_{xx} \cdot f_{yy} - f_{xy}^2$, which can be remembered using $\left| f_{xx}\, f_{xy}\, f_{xy}\, f_{yy} \right|$
